CP/M-68K™ Operating System Release Notes
February 22, 1983

S-RECORD SYSTEMS

Either of the two S-record versions of CP/M-68K included in this release may be combined with a user-supplied BIOS in order to obtain a working CP/M-68K operating system as discussed in the System Guide. In addition to the information given there, you need to know the size and entry points of the S-record systems. The two S-record system files are discussed separately in the following paragraphs.

SR400.SYS resides in memory locations 400H to 5DDFH. You should patch it by placing the 32-bit address of your BIOS's _init entry point at memory locations 4F98H to 4F9BH. Your BIOS can Warm Boot by jumping to 4F9CH.

SR128K.SYS resides in memory locations 15000H to 1A9FFH. You should patch it by placing the 32-bit address of your BIOS's _init entry point at memory locations 19B98H to 19B9BH. Your BIOS can Warm Boot by jumping to 19B9CH.

BUGS

- o The CPM.SYS file on disk 2 of the distribution system was intended to work with a floppy disk EXORmacs™ system. In fact, it does not.
- o AS68 will not operate properly when the disk it is using is full.
- o If you have trouble with AS68, it is likely that you did not initialize it. See the Programmer's Guide for more information.
- o DDT sets up an incorrect command tail when the program under test is specified on the CCP command line invoking DDT rather than using the E and I commands in DDT.

CP/M-68K is a trademark of Digital Research.

EXORmacs is a trademark of Motorola.

Foreword

CP/M-68K™ is a single-user general purpose operating system. It is designed for use with any disk-based computer using a Motorola® MC68000 or compatible processor. CP/M-68K is modular in design, and can be modified to suit the needs of a particular installation.

The hardware interface for a particular hardware environment is supported by the OEM or CP/M-68K distributor. Digital Research supports the user interface to CP/M-68K as documented in the CP/M-68K Operating System User's Guide. Digital Research does not support any additions or modifications made to CP/M-68K by the OEM or distributor.

Purpose and Audience

This manual is intended to provide the information needed by a systems programmer in adapting CP/M-68K to a particular hardware environment. A substantial degree of programming expertise is assumed on the part of the reader, and it is not expected that typical users of CP/M-68K will need or want to read this manual.

Prerequisites and Related Publications

In addition to this manual, the reader should be familiar with the architecture of the Motorola MC68000 as described in the Motorola 16-Bit Microprocessor User's Manual (third edition), the CP/M-68K User's and Programmer's Guides, and, of course, the details of the hardware environment where CP/M-68K is to be implemented.

How This Book is Organized

Section 1 presents an overview of CP/M-68K and describes its major components. Section 2 discusses the adaptation of CP/M-68K for your specific hardware system. Section 3 discusses bootstrap procedures and related information. Section 4 describes each BIOS function including entry parameters and return values. Section 5 describes the process of creating a BIOS for a custom hardware interface. Section 6 discusses how to get CP/M® working for the first time on a new hardware environment. Section 7 describes a procedure for causing a command to be automatically executed on cold boot. Section 8 describes the PUTBOOT utility, which is useful in generating a bootable disk.

Appendix A describes the contents of the CP/M-68K distribution disks. Appendixes B, C, and D are listings of various BIOSes. Appendix E contains a listing of the PUTBOOT utility program. Appendix F describes the Motorola S-record representation for programs.

Section 1

System Overview

1.1 Introduction

CP/M-68K is a single-user, general purpose operating system for microcomputers based on the Motorola MC68000 or equivalent microprocessor chip. It is designed to be adaptable to almost any hardware environment, and can be readily customized for particular hardware systems.

CP/M-68K is equivalent to other CP/M systems with changes dictated by the 68000 architecture. In particular, CP/M-68K supports the very large address space of the 68000 family. The CP/M-68K file system is upwardly compatible with CP/M-80™ version 2.2 and CP/M-86® Version 1.1. The CP/M-68K file structure allows files of up to 32 megabytes per file. CP/M-68K supports from one to sixteen disk drives with as many as 512 megabytes per drive.

The entire CP/M-68K operating system resides in memory at all times, and is not reloaded at a warm start. CP/M-68K can be configured to reside in any portion of memory above the 68000 exception vector area (0H to 3FFH). The remainder of the address space is available for applications programs, and is called the transient program area, TPA.

Several terms used throughout this manual are defined in Table 1-1.

Table 1-1. CP/M-68K Terms

Term	Meaning
nibble	4-bit half-byte
byte	8-bit value
word	16-bit value
longword	32-bit value
address	32-bit identifier of a storage location
offset	a value defining an address in storage; a fixed displacement from some other address

All Information Presented Here is Proprietary to Digital Research

Table 1-1. (continued)

Term	Meaning
text segment	program section containing machine instructions
data segment	program section containing initialized data
block storage segment (bss)	program section containing uninitialized data
absolute	describes a program which must reside at a fixed memory address.
relocatable	describes a program which includes relocation information so it can be loaded into memory at any address

The CP/M-68K programming model is described in detail in the CP/M-68K Operating System Programmer's Guide. To summarize that model briefly, CP/M-68K supports four segments within a program: text, data, block storage segment (bss), and stack. When a program is loaded, CP/M-68K allocates space for all four segments in the TPA, and loads the text and data segments. A transient program may manage free memory using values stored by CP/M-68K in its base page.

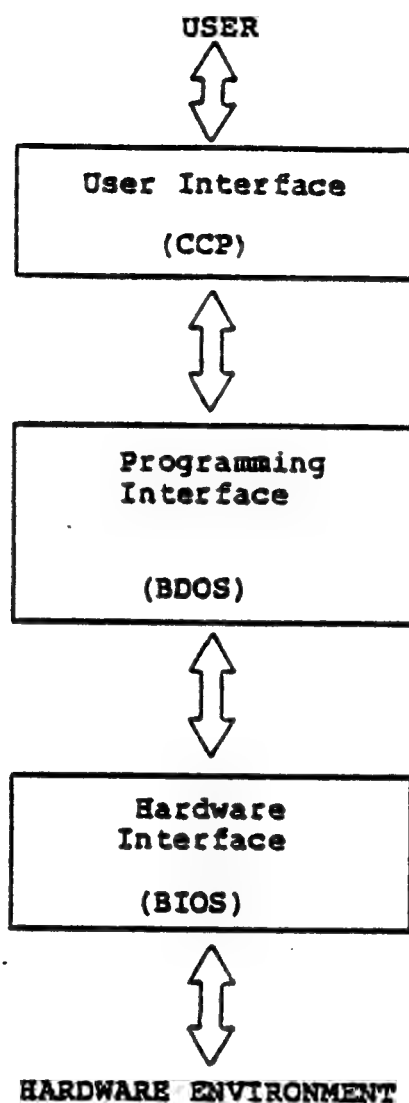

Figure 1-1. CP/M-68K Interfaces

1.2 CP/M-68K Organization

CP/M-68K comprises three system modules: the Console Command Processor (CCP) the Basic Disk Operating System (BDOS) and the Basic Input/Output System (BIOS). These modules are linked together to form the operating system. They are discussed individually in this section.

1.3 Memory Layout

The CP/M-68K operating system can reside anywhere in memory except in the interrupt vector area (0H to 3FFH). The location of CP/M-68K is defined during system generation. Usually, the CP/M-68K operating system is placed at the top end (high address) of available memory, and the TPA runs from 400H to the base of the

All Information Presented Here is Proprietary to Digital Research

operating system. It is possible, however, to have other organizations for memory. For example, CP/M-68K could go in the low part of memory with the TPA above it. CP/M-68K could even be placed in the middle of available memory.

However, because the TPA must be one contiguous piece, part of memory would be unavailable for transient programs in this case. Usually this is wasteful, but such an organization might be useful if an area of memory is to be used for a bit-mapped graphics device, for example, or if there are ROM-resident routines. The BIOS and specialized application programs might know this memory exists, but it is not part of the TPA.

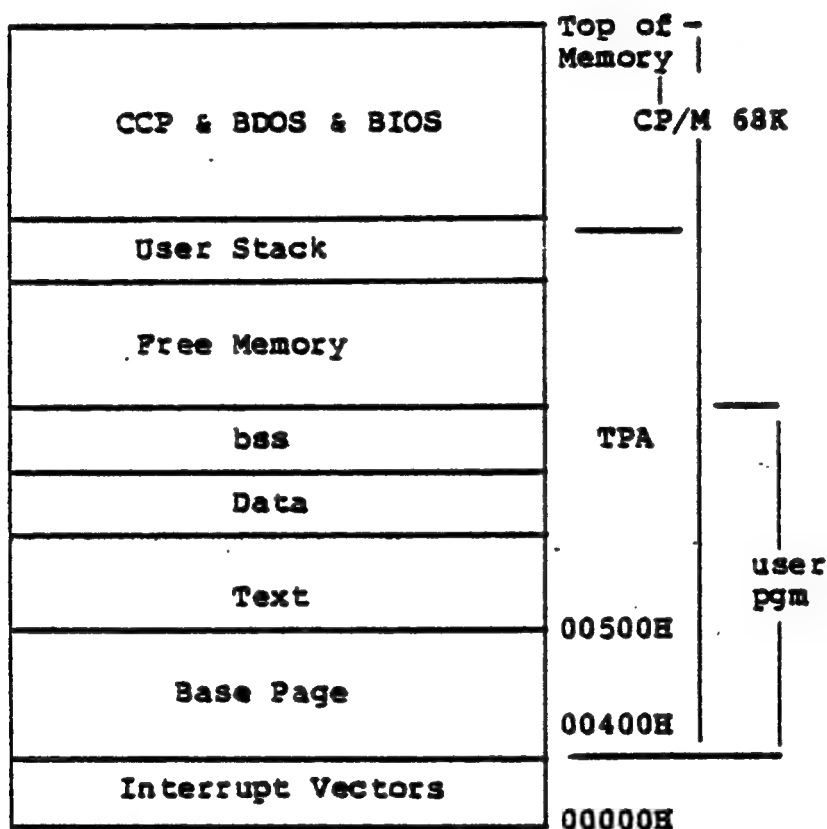

Figure 1-2. Typical CP/M-68K Memory Layout

1.4 Console Command Processor (CCP)

The Console Command Processor, (CCP) provides the user interface to CP/M-68K. It uses the BDOS to read user commands and load programs, and provides several built-in user commands. It also provides parsing of command lines entered at the console.

1.5 Basic Disk Operating System (BDOS)

The Basic Disk Operating System (BDOS) provides operating system services to applications programs and to the CCP. These include character I/O, disk file I/O (the BDOS disk I/O operations comprise the CP/M-68K file system), program loading, and others.

1.6 Basic I/O System (BIOS)

The Basic Input Output System (BIOS) is the interface between CP/M-68K and its hardware environment. All physical input and output is done by the BIOS. It includes all physical device drivers, tables defining disk characteristics, and other hardware specific functions and tables. The CCP and BDOS do not change for different hardware environments because all hardware dependencies have been concentrated in the BIOS. Each hardware configuration needs its own BIOS. Section 4 describes the BIOS functions in detail. Section 5 discusses how to write a custom BIOS. Sample BIOSes are presented in the appendixes.

1.7 I/O Devices

CP/M-68K recognizes two basic types of I/O devices: character devices and disk drives. Character devices are serial devices that handle one character at a time. Disk devices handle data in units of 128 bytes, called sectors, and provide a large number of sectors which can be accessed in random, nonsequential, order. In fact, real systems might have devices with characteristics different from these. It is the BIOS's responsibility to resolve differences between the logical device models and the actual physical devices.

1.7.1 Character Devices

Character devices are input output devices which accept or supply streams of ASCII characters to the computer. Typical character devices are consoles, printers, and modems. In CP/M-68K operations on character devices are done one character at a time. A character input device sends ASCII CTRL-Z (LAH) to indicate end-of-file.

1.7.2 Character Devices

Disk devices are used for file storage. They are organized into sectors and tracks. Each sector contains 128 bytes of data. (If sector sizes other than 128 bytes are used on the actual disk, then the BIOS must do a logical-to-physical mapping to simulate 128-byte sectors to the rest of the system.) All disk I/O in CP/M-68K is done in one-sector units. A track is a group of sectors. The number of sectors on a track is a constant depending on the particular device. (The characteristics of a disk device are specified in the Disk Parameter Block for that device. See

Section 5.) To locate a particular sector, the disk, track number, and sector number must all be specified.

1.8 System Generation and Cold Start Operation

Generating a CP/M-68K system is done by linking together the CCP, BDOS, and BIOS to create a file called CPM.SYS, which is the operating system. Section 2 discusses how to create CPM.SYS. CPM.SYS is brought into memory by a bootstrap loader which will typically reside on the first two tracks of a system disk. (The term system disk as used here simply means a disk with the file CPM.SYS and a bootstrap loader.) Creation of a bootstrap loader is discussed in Section 3.

End of Section 1

Section 2 System Generation

2.1 Overview

This section describes how to build a custom version of CP/M-68K by combining your BIOS with the CCP and BDOS supplied by Digital Research to obtain a CP/M-68K operating system suitable for your specific hardware system. Section 5 describes how to create a BIOS.

In this section, we assume that you have access to an already configured and executable CP/M-68K system. If you do not, you should first read Section 6, which discusses how you can make your first CP/M-68K system work.

A CP/M-68K operating system is generated by using the linker, LO68, to link together the system modules (CCP, BDOS, and BIOS). Then the RELOC utility is used to bind the system to an absolute memory location. The resulting file is the configured operating system. It is named CPM.SYS.

2.2 Creating CPM.SYS

The CCP and BDOS for CP/M-68K are distributed in a library file named CPMLIB. You must link your BIOS with CPMLIB using the following command:

```
A>LO68 -R -UCPM -O CPM.REL CPMLIB BIOS.O
```

where BIOS.O is the compiled or assembled BIOS. This creates CPM.REL, which is a relocatable version of your system. The cold boot loader, however, can load only an absolute version of the system, so you must now create CPM.SYS, an absolute version of your system. If you want your system to reside at the top of memory, first find the size of the system with the following command:

```
A>SIZE68 CPM.REL
```

This gives you the total size of the system in both decimal and hex byte counts. Subtract this number from the highest memory address in your system and add one to get the highest possible address at which CPM.REL can be relocated. Assuming that the result is aaaaaa, type this command:

```
A>RELOC -Baaaaaa CPM.REL CPM.SYS
```

The result is the CPM.SYS file, relocated to load at memory address aaaaaa. If you want CPM.SYS to reside at some other memory address, such as immediately above the exception vector area, you can use RELOC to place the system at that address.

When you perform the relocation, verify that the resulting system does not overlap the TPA as defined in the BIOS. The boundaries of the system are determined by taking the relocation address of CPM.SYS as the base, and adding the size of the system (use SIZE68 on CPM.SYS) to get the upper bound. This address range must not overlap the TPA that the BIOS defines in the Memory Region Table.

2.3 Relocating Utilities

Once you have built CPM.SYS, it is advisable to relocate the operating system utilities for your TPA using the RELOC utility. RELOC is described in the CP/M-68K Operating System Programmer's Guide. This results in the utilities being absolute, rather than relocatable, but they will occupy half the disk space and load into memory twice as fast in their new form. You should also keep the relocatable versions backed up in case you ever need to use them in different TPA.

End of Section 2

Section 3

Bootstrap Procedures

3.1 Bootstrapping Overview

Bootstrap loading is the process of bringing the CP/M-68K operating system into memory and passing control to it. Bootstrap loading is necessarily hardware dependent, and it is not possible to discuss all possible variations in this manual. However, the manual presents a model of bootstrapping that is applicable to most systems.

The model of bootstrapping which we present assumes that the CP/M-68K operating system is to be loaded into memory from a disk in which the first few tracks (typically the first two) are reserved for the operating system and bootstrap routines, while the remainder of the disk contains the file structure, consisting of a directory and disk files. (The topic of disk organization and parameters is discussed in Section 5.) In our model, the CP/M-68K operating system resides in a disk file named CPM.SYS (described in Section 2), and the system tracks contain a bootstrap loader program (CPMLDR.SYS) which knows how to read CPM.SYS into memory and transfer control to it.

Most systems have a boot procedure similar to the following:

- 1) When you press reset, or execute a boot command from a monitor ROM, the hardware loads one or more sectors beginning at track 0, sector 1, into memory at a predetermined address, and then jumps to that address.
- 2) The code that came from track 0, sector 1, and is now executing, is typically a small bootstrap routine that loads the rest of the sectors on the system tracks (containing CPMLDR) into another predetermined address in memory, and then jumps to that address. Note that if your hardware is smart enough, steps 1 and 2 can be combined into one step.
- 3) The code loaded in step 2, which is now executing, is the CP/M Cold Boot Loader, CPMLDR, which is an abbreviated version of CP/M-68K itself. CPMLDR now finds the file CPM.SYS, loads it, and jumps to it. A copy of CPM.SYS is now in memory, executing. This completes the bootstrapping process.

In order to create a CP/M-68K diskette that can be booted, you need to know how to create CPM.SYS (see Section 2.2), how to create the Cold Boot Loader, CPMLDR, and how to put CPMLDR onto your system tracks. You must also understand your hardware enough to be able to design a method for bringing CPMLDR into memory and executing it.

All Information Presented Here is Proprietary to Digital Research

3.2 Creating the Cold Boot Loader

CPMLDR is a miniature version of CP/M-68K. It contains stripped versions of the BDOS and BIOS, with only those functions which are needed to open the CPM.SYS file and read it into memory. CPMLDR will exist in at least two forms; one form is the information in the system tracks, the other is a file named CPMLDR.SYS which is created by the linker. The term CPMLDR is used to refer to either of these forms, but CPMLDR.SYS only refers to the file.

CPMLDR.SYS is generated using a procedure similar to that used in generating CPM.SYS. That is, a loader BIOS is linked with a loader system library, named LDRLIB, to produce CPMLDR.SYS. Additional modules may be linked in as required by your hardware. The resulting file is then loaded onto the system tracks using a utility program named PUTBOOT.

3.2.1 Writing a Loader BIOS

The loader BIOS is very similar to your ordinary BIOS; it just has fewer functions, and the entry convention is slightly different. The differences are itemized below.

- 1) Only one disk needs to be supported. The loader system selects only drive A. If you want to boot from a drive other than A, your loader BIOS should be written to select that other drive when it receives a request to select drive A.
- 2) The loader BIOS is not called through a trap; the loader BDOS calls an entry point named `_bios` instead. The parameters are still passed in registers, just as in the normal BIOS. Thus, your Function 0 does not need to initialize a trap, the code that in a normal BIOS would be the Trap 3 handler should have the label `_bios`, and you exit from your loader BIOS with an RTS instruction instead of an RTE.
- 3) Only the following BIOS functions need to be implemented:
 - 0 (Init) Called just once, should initialize hardware as necessary, no return value necessary. Note that Function 0 is called via `_bios` with the function number equal to 0. You do not need a separate `_init` entry point.
 - 4 (Conout) Used to print error messages during boot. If you do not want error messages, this function should just be an `rts`.
 - 9 (Seldsk) Called just once, to select drive A.
 - 10 (Settrk)

All Information Presented Here is Proprietary to Digital Research

- 11 (Setsec)
 - 12 (Setdma)
 - 13 (Read)
 - 16 (Sectran)
 - 18 (Get MRT) Not used now, but may be used in future releases.
 - 22 (Set exception)
- 4) You do not need to include an allocation vector or a check vector, and the Disk Parameter Header values that point to these can be anything. However, you still need a Disk Parameter Header, Disk Parameter Block, and directory buffer.

It is possible to use the same source code for both your normal BIOS and your loader BIOS if you use conditional compilation or assembly to distinguish the two. We have done this in our example BIOS for the EXORMacs."

3.2.2 Building CPMLDR.SYS

Once you have written and compiled (or assembled) a loader BIOS, you can build CPMLDR.SYS in a manner very similar to building CFM.SYS. There is one additional complication here: the result of this step is placed on the system tracks. So, if you need a small prebooter to bring in the bulk of CPMLDR, the prebooter must also be included in the link you are about to do. The details of what must be done are hardware dependent, but the following example should help to clarify the concepts involved.

Suppose that your hardware reads track 0, sector 1, into memory at location 400H when reset is pressed, then jump to 400H. Then your boot disk must have a small program in that sector that can load the rest of the system tracks into memory and execute the code that they contain. Suppose that you have written such a program, assembled it, and the assembler output is in BOOT.O. Also assume that your loader BIOS object code is in the file LDRBIOS.O. Then the following command links together the code that must go on the system tracks.

```
A>lo68 -s -T400 -uldr -o cpmlldr.sys boot.o ldrlib ldrbios.o
```

Once you have created CPMLDR.SYS in this way, you can use the PUTBOOT utility to place it on the system tracks. PUTBOOT is described in Section 8. The command to place CPMLDR on the system tracks of drive A is:

```
A>putboot cpmlldr.sys a
```

All Information Presented Here is Proprietary to Digital Research

PUTBOOT reads the file CPMLDR.SYS, strips off the 28-byte command file header, and puts the result on the specified drive. You can now boot from this disk, assuming that CPM.SYS is on the disk.

End of Section 3

Section 4 BIOS Functions

4.1 Introduction

All CP/M-68K hardware dependencies are concentrated in subroutines that are collectively referred to as the Basic I/O System (BIOS). A CP/M-68K system implementor can tailor CP/M-68K to fit nearly any 68000 operating environment. This section describes each BIOS function: its calling conventions, parameters, and the actions it must perform. The discussion of Disk Definition Tables is treated separately in Section 5.

When the BDOS calls a BIOS function, it places the function number in register D0.W, and function parameters in registers D1 and D2. It then executes a TRAP 3 instruction. D0.W is always needed to specify the function, but each function has its own requirements for other parameters, which are described in the section describing the particular function. The BIOS returns results, if any, in register D0. The size of the result depends on the particular function.

Note: the BIOS does not need to preserve the contents of registers. That is, any register contents which were valid on entry to the BIOS may be destroyed by the BIOS on exit. The BDOS does not depend on the BIOS to preserve the contents of data or address registers. Of course, if the BIOS uses interrupts to service I/O, the interrupt handlers will need to preserve registers.

Usually, user applications do not need to make direct use of BIOS functions. However, when access to the BIOS is required by user software, it should use the BDOS Direct BIOS Function, Call 50, instead of calling the BIOS with a TRAP 3 instruction. This rule ensures that applications remain compatible with future systems.

The Disk Parameter Header (DPH) and Disk Parameter Block (DPB) formats have changed slightly from previous CP/M versions to accommodate the 68000's 32-bit addresses. The formats are described in Section 5.

Table 4-1. BIOS Register Usage

Entry Parameters:
D0.W = function code D1.x = first parameter D2.x = second parameter
Return Values:
D0.B = byte values (8 bits) D0.W = word values (16 bits) D0.L = longword values (32 bits)

The decimal BIOS function numbers and the functions they correspond to are listed in Table 4-2.

Table 4-2. BIOS Functions

Number	Function
0	Initialization (called for cold boot)
1	Warm Boot (called for warm start)
2	Console Status (check for console character ready)
3	Read Console Character In
4	Write Console Character Out
5	List (write listing character out)
6	Auxiliary Output (write character to auxiliary output device)
7	Auxiliary Input (read from auxiliary input)
8	Home (move to track 00)
9	Select Disk Drive
10	Set Track Number
11	Set Sector Number
12	Set DMA Address
13	Read Selected Sector
14	Write Selected Sector
15	Return List Status
16	Sector Translate
18	Get Memory Region Table Address
19	Get I/O Mapping Byte
20	Set I/O Mapping Byte
21	Flush Buffers
22	Set Exception Handler Address

FUNCTION 0: INITIALIZATION
Entry Parameters: Register D0.W: 00H
Returned Value: Register D0.W: User/Disk Numbers

This routine is entered on cold boot and must initialize the BIOS. Function 0 is unique, in that it is not entered with a TRAP 3 instruction. Instead, the BIOS has a global label, `_init`, which is the entry to this routine. On cold boot, Function 0 is called by a `jsr _init`. When initialization is done, exit is through an `rts` instruction. Function 0 is responsible for initializing hardware if necessary, initializing BIOS internal variables (such as `IOBYTE`) as needed, setting up register D0 as described below, setting the Trap 3 vector to point to the main BIOS entry point, and then exiting with an `rts`.

Function 0 returns a longword value. The CCP uses this value to set the initial user number and the initial default disk drive. The least significant byte of D0 is the disk number (0 for drive A, 1 for drive B, and so on). The next most significant byte is the user number. The high-order bytes should be zero.

The entry point to this function must be named `_init` and must be declared global. This function is called only once from the system at system initialization.

Following is an example of skeletal code:

```
.globl    _init    ;bios init entry point

_init:
    do any initialization here
    move.l    #trapnd1,$8c    ;set trap 3 handler
    clr.l     d0              ;login drive A, user 0
    rts
```

FUNCTION 1: WARM BOOT
Entry Parameters: Register D0.W: 01H
Returned Value: None

This function is called whenever a program terminates. Some reinitialization of the hardware or software might occur. When this function completes, it jumps directly to the entry point of the CCP, named `_ccp`. Note that `_ccp` must be declared as a global.

Following is an example of skeletal code for this BIOS function:

```
        .globl    _ccp
wboot:
* do any reinitialization here if necessary
        jmp      _ccp
```

FUNCTION 2: CONSOLE STATUS	
Entry Parameters:	Register D0.W: 02H
Returned Value:	Register D0.W: 00FFH if ready Register D0.W: 0000H if not ready

This function returns the status of the currently assigned console device. It returns 00FFH in register D0 when a character is ready to be read, or 0000H in register D0 when no console characters are ready.

FUNCTION 3: READ CONSOLE CHARACTER
Entry Parameters: Register D0.W: 03H
Returned Value: Register D0.W: Character

This function reads the next console character into register D0.W. If no console character is ready, it waits until a character is typed before returning.

FUNCTION 4: WRITE CONSOLE CHARACTER
Entry Parameters: Register D0.W: 04H Register D1.W: Character
Returned Value: None

This function sends the character from register D1 to the console output device. The character is in ASCII. You might want to include a delay or filler characters for a line-feed or carriage return, if your console device requires some time interval at the end of the line (such as a TI Silent 700 Terminal®). You can also filter out control characters which have undesirable effects on the console device.

FUNCTION 5: LIST CHARACTER OUTPUT
Entry Parameters: Register D0.W: 05H Register D1.W: Character
Returned Value: None

This function sends an ASCII character from register D1 to the currently assigned listing device. If your list device requires some communication protocol, it must be handled here.

FUNCTION 6: AUXILIARY OUTPUT
Entry Parameters: Register D0.W: 06H Register D1.W: Character
Returned Value: Register D0.W: Character

This function sends an ASCII character from register D1 to the currently assigned auxiliary output device.

FUNCTION 7: AUXILIARY INPUT
Entry Parameters: Register D0.W: 07H
Returned Value: Register D0.W: Character

This function reads the next character from the currently assigned auxiliary input device into register D0. It reports an end-of-file condition by returning an ASCII CTRL-Z (1AH).

FUNCTION 8: HOME
Entry Parameters: Register D0.W: 08H
Returned Value: None

This function returns the disk head of the currently selected disk to the track 00 position. If your controller does not have a special feature for finding track 00, you can translate the call to a SETTRK function with a parameter of 0.

FUNCTION 9: SELECT DISK DRIVE	
Entry Parameters:	
Register D0.W:	09H
Register D1.B:	Disk Drive
Register D2.B:	Logged in Flag
Returned Value:	
Register D0.L:	Address of Selected Drive's DPH

This function selects the disk drive specified in register D1 for further operations. Register D1 contains 0 for drive A, 1 for drive B, up to 15 for drive P.

On each disk select, this function returns the address of the selected drive's Disk Parameter Header in register D0.L. See Section 5 for a discussion of the Disk Parameter Header.

If there is an attempt to select a nonexistent drive, this function returns 00000000H in register D0.L as an error indicator. Although the function must return the header address on each call, it may be advisable to postpone the actual physical disk select operation until an I/O function (seek, read, or write) is performed. Disk select operations can occur without a subsequent disk operation. Thus, doing a physical select each time this function is called may be wasteful of time.

On entry to the Select Disk Drive function, if the least significant bit in register D2 is zero, the disk is not currently logged in. If the disk drive is capable of handling varying media (such as single- and double-sided disks, single- and double-density, and so on), the BIOS should check the type of media currently installed and set up the Disk Parameter Block accordingly at this time.

FUNCTION 10: SET TRACK NUMBER	
Entry Parameters:	
Register D0.W:	0AH
Register D1.W:	Disk track number
Returned Value:	None

This function specifies in register D0.W the disk track number for use in subsequent disk accesses. The track number remains valid until either another Function 10 or a Function 8 (Home) is performed.

You can choose to physically seek to the selected track at this time, or delay the physical seek until the next read or write actually occurs.

The track number can range from 0 to the maximum track number supported by the physical drive. However, the maximum track number is limited to 65535 by the fact that it is being passed as a 16-bit quantity. Standard floppy disks have tracks numbered from 0 to 76.

FUNCTION 11: SET SECTOR NUMBER

Entry Parameters:

Register D0.W: 0BH

Register D1.W: Sector Number

Returned Value: None

This function specifies in register D1.W the sector number for subsequent disk accesses. This number remains in effect until either another Function 11 is performed.

The function selects actual (unskewed) sector numbers. If skewing is appropriate, it will have previously been done by a call to Function 16. You can send this information to the controller at this point or delay sector selection until a read or write operation occurs.

FUNCTION 12: SET DMA ADDRESS	
Entry Parameters:	
Register D0.W:	0CH
Register D1.L:	DMA Address
Returned Value:	None

This function contains the DMA (disk memory access) address in register D1 for subsequent read or write operations. Note that the controller need not actually support DMA (direct memory access). The BIOS will use the 128-byte area starting at the selected DMA address for the memory buffer during the following read or write operations. This function can be called with either an even or an odd address for a DMA buffer.

FUNCTION 13: READ SECTOR	
Entry Parameters:	Register D0.W: 0DH
Returned Value:	Register D0.W: 0 if no error Register D0.W: 1 if physical error

After the drive has been selected, the track has been set, the sector has been set, and the DMA address has been specified, the read function uses these parameters to read one sector and returns the error code in register D0.

Currently, CP/M-68K responds only to a zero or nonzero return code value. Thus, if the value in register D0 is zero, CP/M-68K assumes that the disk operation completed properly. If an error occurs however, the BIOS should attempt at least ten retries to see if the error is recoverable.

FUNCTION 14: WRITE SECTOR	
Entry Parameters:	
Register D0.W:	0EH
Register D1.W:	0=normal write 1=write to a directory sector 2=write to first sector of new block
Returned Value:	
Register D0.W:	0=no error 1=physical error

This function is used to write 128 bytes of data from the currently selected DMA buffer to the currently selected sector, track, and disk. The value in register D1.W indicates whether the write is an ordinary write operation or whether there are special considerations.

If register D1.W=0, this is an ordinary write operation. If D1.W=1, this is a write to a directory sector, and the write should be physically completed immediately. If D1.W=2, this is a write to the first sector of a newly allocated block of the disk. The significance of this value is discussed in Section 5 under Disk Buffering.

FUNCTION 15: RETURN LIST STATUS
Entry Parameters: Register D0.W: 0FH
Returned Value: Register D0: 00FFH=device ready Register D0: 0000H=device not ready

This function returns the status of the list device. Register D0 contains either 0000H when the list device is not ready to accept a character or 00FFH when a character can be sent to the list device.

FUNCTION 16: SECTOR TRANSLATE
Entry Parameters: Register D0.W: 10H Register D1.W: Logical Sector Number Register D2.L: Address of Translate Table
Returned Value: Register D0.W: Physical Sector Number

This function performs logical-to-physical sector translation, as discussed in Section 5.2.2. The Sector Translate function receives a logical sector number from register D1.W. The logical sector number can range from 0 to the number of sectors per track-1. Sector Translate also receives the address of the translate table in register D2.L. The logical sector number is used as an index into the translate table. The resulting physical sector number is returned in D0.W.

If register D2.L = 00000000H, implying that there is no translate table, register D1 is copied to register D0 before returning. Note that other algorithms are possible; in particular, it is common to increment the logical sector number in order to convert the logical range of 0 to n-1 into the physical range of 1 to n. Sector Translate is always called by the BDOS, whether the translate table address in the Disk Parameter Header is zero or nonzero.

FUNCTION 18: GET ADDRESS OF MEMORY REGION TABLE
Entry Parameters: Register D0.W: 12H
Returned Value: Register D0.L: Memory Region Table Address

This function returns the address of the Memory Region Table (MRT) in register D0. For compatibility with other CP/M systems, P/M-68K maintains a Memory Region Table. However, it contains only one region, the Transient Program Area (TPA). The format of the MRT is shown below:

Entry Count = 1	16 bits
Base address of first region	32 bits
Length of first region	32 bits

Figure 4-1. Memory Region Table Format

The memory region table must begin on an even address, and must be implemented.

FUNCTION 19: GET I/O BYTE
Entry Parameters: Register D0.W: 13H
Returned Value: Register D0.W: I/O Byte Current Value

This function returns the current value of the logical to physical input/output device byte (I/O byte) in register D0.W. This 8-bit value associates physical devices with CP/M-68K's four logical devices as noted below. Note that even though this is a byte value, we are using word references. The upper byte should be zero.

Peripheral devices other than disks are seen by CP/M-68K as logical devices, and are assigned to physical devices within the BIOS. Device characteristics are defined in Table 4-3 below.

Table 4-3. CP/M-68K Logical Device Characteristics

Device Name	Characteristics
CONSOLE	The interactive console that you use to communicate with the system is accessed through functions 2, 3 and 4. Typically, the console is a CRT or other terminal device.
LIST	The listing device is a hard-copy device, usually a printer.
AUXILIARY OUTPUT	An optional serial output device.
AUXILIARY INPUT	An optional serial input device.

Note that a single peripheral can be assigned as the LIST, AUXILIARY INPUT, and AUXILIARY OUTPUT device simultaneously. If no peripheral device is assigned as the LIST, AUXILIARY INPUT, or AUXILIARY OUTPUT device, your BIOS should give an appropriate error message so that the system does not hang if the device is accessed by PIP or some other transient program. Alternatively, the AUXILIARY OUTPUT and LIST functions can simply do nothing except return to the caller, and the AUXILIARY INPUT function can return with a -LAH (CTRL-Z) in register D0.W to indicate immediate end-of-file.

The I/O byte is split into four 2-bit fields called **CONSOLE**, **AUXILIARY INPUT**, **AUXILIARY OUTPUT**, and **LIST**, as shown in Figure 4-2.

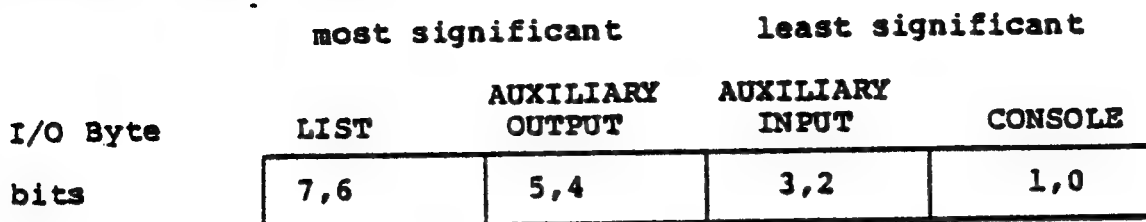

Figure 4-3. I/O Byte

The value in each field can be in the range 0-3, defining the assigned source or destination of each logical device. The values which can be assigned to each field are given in Table 4-4.

Table 4-4. I/O Byte Field Definitions

CONSOLE field (bits 1,0)	
Bit	Definition
0	console is assigned to the console printer (TTY:)
1	console is assigned to the CRT device (CRT:)
2	batch mode: use the AUXILIARY INPUT as the CONSOLE input, and the LIST device as the CONSOLE output (BAT:)
3	user defined console device (UC1:)
AUXILIARY INPUT field (bits 3,2)	
Bit	Definition
0	AUXILIARY INPUT is the Teletype device (TTY:)
1	AUXILIARY INPUT is the high-speed reader device (PTR:)
2	user defined reader #1 (UR1:)
3	user defined reader #2 (UR2:)

Table 4-4. (continued)

AUXILIARY OUTPUT field (bits 5,4)	
Bit	Definition
0	AUXILIARY OUTPUT is the Teletype device (TTY:)
1	AUXILIARY OUTPUT is the high-speed punch device (PTP:)
2	user defined punch #1 (UP1:)
3	user defined punch #2 (UP2:)
LIST field (bits 7,6)	
Bit	Definition
0	LIST is the Teletype device (TTY:)
1	LIST is the CRT device (CRT:)
2	LIST is the line printer device (LPT:)
3	user defined list device (UL1:)

Note that the implementation of the I/O byte is optional, and affects only the organization of your BIOS. No CP/M-68K utilities use the I/O byte except for PIP, which allows access to the physical devices, and STAT, which allows logical-physical assignments to be made and displayed. It is a good idea to first implement and test your BIOS without the IOBYTE functions, then add the I/O byte function.

FUNCTION 20: SET I/O BYTE	
Entry Parameters:	
Register D0.W:	14H
Register D1.W:	Desired
Returned	Value: None

This function uses the value in register D1 to set the value of the I/O byte that is stored in the BIOS. See Table 4-4 for the I/O byte field definitions. Note that even though this is a byte value, we are using word references. The upper byte should be zero.

FUNCTION 21: FLUSH BUFFERS	
Entry Parameters:	Register D0.W: 15H
Returned Value:	Register D0.W: 0000H=successful write Register D0.W: FFFFH=unsuccessful write

This function forces the contents of any disk buffers that have been modified to be written. That is, after this function has been performed, all disk writes have been physically completed. After the buffers are written, this function returns a zero in register D0.W. However, if the buffers cannot be written or an error occurs, the function returns a value of FFFFH in register D0.W.

FUNCTION 22: SET EXCEPTION HANDLER ADDRESS
Entry Parameters: Register D0.W: 16H Register D1.W: Exception Vector Number Register D2.L: Exception Vector Address
Returned Value: Register D0.L: Previous Vector Contents

This function sets the exception vector indicated in register D1.W to the value specified in register D2.L. The previous vector value is returned in register D0.L. Unlike the BDOS Set Exception Vector Function (61), this BIOS function sets any exception vector. Note that register D1.W contains the exception vector number. Thus, to set exception #2, bus error, this register contains a 2, and the vector value goes to memory locations 08H to 0BH.

End of Section 4

Section 5 Creating a BIOS

5.1 Overview

The BIOS provides a standard interface to the physical input/output devices in your system. The BIOS interface is defined by the functions described in Section 4. Those functions, taken together, constitute a model of the hardware environment. Each BIOS is responsible for mapping that model onto the real hardware.

In addition, the BIOS contains disk definition tables which define the characteristics of the disk devices which are present, and provides some storage for use by the BDOS in maintaining disk directory information.

Section 4 describes the functions which must be performed by the BIOS, and the external interface to those functions. This Section contains additional information describing the structure and significance of the disk definition tables and information about sector blocking and deblocking. Careful choices of disk parameters and disk buffering methods are necessary if you are to achieve the best possible performance from CP/M-68K. Therefore, this section should be read thoroughly before writing a custom BIOS.

CP/M-68K, as distributed by Digital Research, is configured to run on the Motorola EXORmacs development system with Universal Disk Controller. The sample BIOS in Appendix D is the BIOS used in the distributed system, and is written in C language. A sample BIOS for an Empirical Research Group (ERG) 68000 based microcomputer with Tarbell floppy disk controller is also included in Appendix B, and is written in assembly language. These examples should assist the reader in understanding how to construct his own BIOS.

5.2 Disk Definition Tables

As in other CP/M systems, CP/M-68K uses a set of tables to define disk device characteristics. This section describes each of these tables and discusses choices of certain parameters.

5.2.1 Disk Parameter Header

Each disk drive has an associated 26-byte Disk Parameter Header (DPH) which both contains information about the disk drive and provides a scratchpad area for certain BDOS operations. Each drive must have its own unique DPH. The format of a Disk Parameter Header is shown in Figure 5-1.

2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25

XLT	0000	0000	0000	DIRBUF	DPB	CSV	ALV
32b	16b	16b	16b	32b	32b	32b	32b

Figure 5-1. Disk Parameter Header

Each element of the DPH is either a word (16-bit) or longword (32-bit) value. The meanings of the Disk Parameter Header (DPH) elements are given in Table 5-1.

Table 5-1. Disk Parameter Header Elements

Element	Description
XLT	Address of the logical-to-physical sector translation table, if used for this particular drive, or the value 0 if there is no translation table for this drive (i.e., the physical and logical sector numbers are the same). Disk drives with identical sector translation may share the same translate table. The sector translation table is described in Section 5.2.2.
0000	Three scratchpad words for use within the BDOS.
DIRBUF	Address of a 128-byte scratchpad area for directory operations within BDOS. All DPHs address the same scratchpad area.
DPB	Address of a disk parameter block for this drive. Drives with identical disk characteristics may address the same disk parameter block.

Table 5-1. (continued)

Element	Description
CSV	Address of a checksum vector. The BDOS uses this area to maintain a vector of directory checksums for the disk. These checksums are used in detecting when the disk in a drive has been changed. If the disk is not removable, then it is not necessary to have a checksum vector. Each DPH must point to a unique checksum vector. The checksum vector should contain 1 byte for every four directory entries (or 128 bytes of directory). In other words: length (CSV) = $(\text{DRM}+1) / 4$. (DRM is discussed in Section 5.2.3.)
ALV	Address of a scratchpad area used by the BDOS to keep disk storage allocation information. The area must be different for each DPH. There must be 1 bit for each allocation block on the drive, requiring the following: length (ALV) = $(\text{DSM}/8) + 1$. (DSM is discussed below.)

5.2.2 Sector Translate Table

Sector translation in CP/M-68K is a method of logically renumbering the sectors on each disk track to improve disk I/O performance. A frequent situation is that a program needs to access disk sectors sequentially. However, in reading sectors sequentially, most programs lose a full disk revolution between sectors because there is not enough time between adjacent sectors to begin a new disk operation. To alleviate this problem, the traditional CP/M solution is to create a logical sector numbering scheme in which logically sequential sectors are physically separated. Thus, between two logically contiguous sectors, there is a several sector rotational delay. The sector translate table defines the logical-to-physical mapping in use for a particular drive, if a mapping is used.

Sector translate tables are used only within the BIOS. Thus the table may have any convenient format. (Although the BDOS is aware of the sector translate table, its only interaction with the table is to get the address of the sector translate table from the DPH and to pass that address to the Sector Translate Function of the BIOS.) The most common form for a sector translate table is an n-byte (or n-word) array of physical sector numbers, where n is the number of sectors per disk track. Indexing into the table with the logical sector number yields the corresponding physical sector number.

Although you may choose any convenient logical-to-physical mapping, there is a nearly universal mapping used in the CP/M community for single-sided, single-density, 8-inch diskettes. That mapping is shown in Figure 5-2. Because your choice of mapping affects diskette compatibility between different systems, the mapping of Figure 5-2 is strongly recommended.

Logical Sector	0	1	2	3	4	5	6	7	8	9	10	11	12
Physical Sector	1	7	13	19	25	5	11	17	23	3	9	15	21
Logical Sector	13	14	15	16	17	18	19	20	21	22	23	24	25
Physical Sector	2	8	14	20	26	6	12	18	24	4	10	16	22

Figure 5-2. Sample Sector Translate Table

2.3 Disk Parameter Block

A Disk Parameter Block (DPB) defines several characteristics associated with a particular disk drive. Among them are the size of the drive, the number of sectors per track, the amount of directory space, and others.

A Disk Parameter Block can be used in one or more DPH's if the disks are identical in definition. A discussion of the fields of the DPB follows the format description. The format of the DPB is shown in Figure 5-3.

SPT	BSH	BLM	EXM	0	DSM	DRM	Reserved	CKS	OFF
16b	8b	8b	8b	8b	16b	16b	16b	16b	16b

Figure 5-3. Disk Parameter Block

Each field is a word (16 bit) or a byte (8 bit) value. The description of each field is given in Table 5-2.

Table 5-2. Disk Parameter Block Fields

Field	Definition
SPT	Number of 128-byte logical sectors per track.
BSH	The block shift factor, determined by the data block allocation size, as shown in Table 5-3.

All Information Presented Here is Proprietary to Digital Research

Table 5-2. (continued)

Field	Definition
BLM	The block mask which is determined by the data block allocation size, as shown in Table 5-3.
EXM	The extent mask, determined by the data block allocation size and the number of disk blocks, as shown in Table 5-4.
0	Reserved byte.
DSM	Determines the total storage capacity of the disk drive and is the number of the last block, counting from 0. That is, the disk contains DSM+1 blocks.
DRM	Determines the total number of directory entries which can be stored on this drive. DRM is the number of the last directory entry, counting from 0. That is, the disk contains DRM+1 directory entries. Each directory entry requires 32 bytes, and for maximum efficiency, the value of DRM should be chosen so that the directory entries exactly fill an integral number of allocation units.
CKS	The size of the directory check vector, which is zero if the disk is permanently mounted, or length (CSV) = $(\text{DRM} + 1) / 4$ for removable media.
OFF	The number of reserved tracks at the beginning of a logical disk. This is the number of the track on which the directory begins.

To choose appropriate values for the Disk Parameter Block elements, you must understand how disk space is organized in CP/M-68K. A CP/M-68K disk has two major areas: the boot or system tracks, and the file system tracks. The boot tracks are usually used to hold a machine-dependent bootstrap loader for the operating system. They consist of tracks 0 to OFF-1. Zero is a legal value for OFF, and in that case, there are no boot tracks. The usual value of OFF for 8-inch floppy disks is two.

The tracks after the boot tracks (beginning with track number OFF) are used for the disk directory and disk files. Disk space in this area is grouped into units called allocation units or blocks. The block size for a particular disk is a constant, called BLS. BLS may take on any one of these values: 1024, 2048, 4096, 8192, or 16384 bytes. No other values for BLS are allowed. (Note that BLS does not appear explicitly in any BIOS table. However, it determines the values of a number of other parameters.) The DSM field in the Disk Parameter Block is one less than the number of

All Information Presented Here is Proprietary to Digital Research

blocks on the disk. Space is allocated to a file or to the directory in whole blocks. No fraction of a block can be allocated. block size

The choice of BLS is very important, because it effects the efficiency of disk space utilization, and because for any disk size there is a minimum value of BLS that allows the entire disk to be used. Each block on the disk has a block number ranging from 0 to DSM. The largest block number allowed is 32767. Therefore, the largest number of bytes that can be addressed in the file system space is $32768 * BLS$. Because the largest allowable value for BLS is 16384, the biggest disk that can be accessed by CP/M-68K is $16384 * 32768 = 512$ Mbytes.

Each directory entry may contain either 8 block numbers (if $DSM \geq 256$) or 16 block numbers (if $DSM < 256$). Each file needs enough directory entries to hold the block numbers of all blocks allocated to the file. Thus a large value for BLS implies that fewer directory entries are needed. Since fewer directory entries are needed, the directory search time is decreased.

The disadvantage of a large value for BLS is that since files are allocated BLS bytes at a time, there is potentially a large unused portion of a block at the end of the file. If there are many small files on a disk, the waste can be very significant.

The BSH and BLM parameters in the DPB are functions of BLS. Once you have chosen BLS, you should use Table 5-3 to determine BSH and BLM. The EXM parameter of the DPB is a function of BLS and DSM. You should use Table 5-4 to find the value of EXM for your disk.

Table 5-3. BSH and BLM Values

BLS	BSH	BLM
1024	3	7
2048	4	15
4096	5	31
8192	6	63
16384	7	127

Table 5-4. EXM Values

BLS	DSM \leq 255	DSM $>$ 255
1024	0	N/A
2048	1	0
4096	3	1
8192	7	3
16384	15	7

The DRM entry in the DPB is one less than the total number of directory entries. DRM should be chosen large enough so that you do not run out of directory entries before running out of disk space. It is not possible to give an exact rule for determining DRM, since the number of directory entries needed will depend on the number and sizes of the files present on the disk.

The CKS entry in the DPB is the number of bytes in the CSV (checksum vector) which was pointed to by the DPH. If the disk is not removable, a checksum vector is not needed, and this value may be zero.

5.3 Disk Blocking

When the BDOS does a disk read or write operation using the BIOS, the unit of information read or written is a 128-byte sector. This may or may not correspond to the actual physical sector size of the disk. If not, the BIOS must implement a method of representing the 128-byte sectors used by CP/M-68K on the actual device. Usually if the physical sectors are not 128 bytes long, they will be some multiple of 128 bytes. Thus, one physical sector can hold some integer number of 128-byte CP/M sectors. In this case, any disk I/O will actually consist of transferring several CP/M sectors at once.

It might also be desirable to do disk I/O in units of several 128-byte sectors in order to increase disk throughput by decreasing rotational latency. (Rotational latency is the average time it takes for the desired position on a disk to rotate around to the read/write head. Generally this averages 1/2 disk revolution per transfer.) Since a great deal of disk I/O is sequential, rotational latency can be greatly reduced by reading several sectors at a time, and saving them for future use.

In both the cases above, the point of interest is that physical I/O occurs in units larger than the expected sector size of 128 bytes. Some of the problems in doing disk I/O in this manner are discussed below.

5.3.1 A Simple Approach

This section presents a simple approach to handling a physical sector size larger than the logical sector size. The method discussed in this section is not recommended for use in a real BIOS. Rather, it is given as a starting point for refinements discussed in the following sections. Its simplicity also makes it a logical choice for a first BIOS on new hardware. However, the disk throughput that you can achieve with this method is poor, and the refinements discussed later give dramatic improvements.

Probably the easiest method for handling a physical sector size which is a multiple of 128 bytes is to have a single buffer the size of the physical sector internal to the BIOS. Then, when a disk read is to be done, the physical sector containing the desired 128-byte logical sector is read into the buffer, and the appropriate 128 bytes are copied to the DMA address. Writing is a little more complicated. You only want to put data into a 128-byte portion of the physical sector, but you can only write a whole physical sector. Therefore, you must first read the physical sector into the BIOS's buffer; copy the 128 bytes of output data into the proper 128-byte piece of the physical sector in the buffer; and finally write the entire physical sector back to disk.

Note: this operation involves two rotational latency delays in addition to the time needed to copy the 128 bytes of data. In fact, the second rotational wait is probably nearly a full disk revolution, since the copying is usually much faster than a disk revolution.

5.3.2 Some Refinements

There are some easy things that can be done to the algorithm of Section 5.2.1 to improve its performance. The first is based on the fact that disk accesses are usually done sequentially. Thus, if data from a certain physical sector is needed, it is likely that another piece of that sector will be needed on the next disk operation. To take advantage of this fact, the BIOS can keep information with its physical sector buffer as to which disk, track, and physical sector (if any) is represented in the buffer. Then, when reading, the BIOS need only do physical disk reads when the information needed is not in the buffer.

On writes, the BIOS still needs to preread the physical sector for the same reasons discussed in Section 5.2.1, but once the physical sector is in the buffer, subsequent writes into that physical sector do not require additional prereads. An additional saving of disk accesses can be gained by not writing the sector to the disk until absolutely necessary. The conditions under which the physical sector must be written are discussed in Section 5.3.4.

5.3.3 Track Buffering

Track buffering is a special case of disk buffering where the I/O is done a full track at a time. When sufficient memory for several full track buffers is available, this method is quite good. The method is essentially the same as discussed in Section 5.3.2, but there are some interesting features. First, transferring an entire track is much more efficient than transferring a single sector. The rotational latency is incurred only once for the entire track, whereas if the track is transferred one sector at a time, the rotational latency occurs once per sector. On a typical diskette with 26 sectors per track, rotating at 6 revolutions per second, the difference in rotational latency per track is about 2 seconds versus a twelfth of a second. Of course, in applications where the disk is accessed purely randomly, there is no advantage because there is a low probability that more than one sector will be used from a given track. However, such applications are extremely rare.

5.3.4 LRU Replacement

With any method of disk buffering using more than one buffer, it is necessary to have some algorithm for managing the buffers. That is, when should buffers be filled, and when should they be written back to disk. The first question is simple, a buffer should be filled when there is a request for a disk sector that is not presently in memory. The second issue, when to write a buffer back to disk, is more complicated.

Generally, it is desirable to defer writing a buffer until it becomes necessary. Thus, several transfers can be done to a buffer for the cost of only one disk access, two accesses if the buffer had to be pre-read. However, there are several reasons why buffers must be written. The following list describes the reasons:

- 1) A BIOS Write operation with mode=1 (write to directory sector). To maintain the integrity of CP/M-68K's file system, it is very important that directory information on the disk is kept up to date. Therefore, all directory writes should be performed immediately.
- 2) A BIOS Flush Buffers operation. This BIOS function is explicitly intended to force all disk buffers to be written. After performing a Flush Buffers, it is safe to remove a disk from its drive.
- 3) A disk buffer is needed, but all buffers are full. Therefore some buffer must be emptied to make it available for reuse.
- 4) A Warm Boot occurs. This is similar to number 2 above.

Case three above is the only one in which the BIOS writer has any discretion as to which buffer should be written. Probably the best strategy is to write out the buffer which has been least recently used. The fact that an area of disk has not been accessed for some time is a fairly good indication that it will not be needed again soon.

5.3.5 The New Block Flag

As explained in Section 5.2.2, the BDOS allocates disk space to files in blocks of BLS bytes. When such a block is first allocated to a file, the information previously in that block need not be preserved. To enable the BIOS to take advantage of this fact, the BDOS uses a special parameter in calling the BIOS Write Function. If register DL.W contains the value 2 on a BIOS Write call, then the write being done is to the first sector of a newly allocated disk block. Therefore, the BIOS need not preread any sector of that block. If the BIOS does disk buffering in units of BLS bytes, it can simply mark any free buffer as corresponding to the disk address specified in this write, because the contents of the newly allocated block are not important. If the BIOS uses a buffer size other than BLS, then the algorithm for taking full advantage of this information is more complicated.

This information is extremely valuable in reducing disk delays. Consider the case where one file is read sequentially and copied to a newly created file. Without the information about newly allocated disk blocks, every physical write would require a preread. With the information, no physical write requires a preread. Thus, the number of physical disk operations is reduced by one third.

End of Section 5

Section 6

Installing and Adapting the Distributed BIOS and CP/M-68K

6.1 Overview

The process of bringing up your first running CP/M-68K system is either trivial or involved, depending on your hardware environment. Digital Research supplies CP/M-68K in a form suitable for booting on a Motorola EXORMacs development system. If you have an EXORMacs, you can read Section 6.1 which tells how to load the distributed system. Similarly, you can buy or lease some other machine which already runs CP/M-68K.

If you do not have an EXORMacs, you can use the S-record files supplied with your distribution disks to bring up your first CP/M-68K system. This process is discussed in Section 6.2.

6.2 Booting on an EXORMacs

The CP/M-68K disk set distributed by Digital Research includes disks boot and run CP/M-68K on the Motorola EXORMacs. You can use the distribution system boot disk without modification if you have a Motorola EXORMacs system and the following configuration:

- 1) 128K memory (minimum)
- 2) a Universal Disk Controller (UDC) or Floppy Disk Controller (FDC)
- 3) a single-density, IBM 3740 compatible floppy disk drive
- 4) an EXORterm

To load CP/M-68K, do the following:

- 1) Place the disk in the first floppy drive (#FD04 with the UDC or #FD00 with the FDC).
- 2) Press SYSTEM RESET (front panel) and RETURN (this brings in MACSbug).
- 3) Type "BO 4" if you are using the UDC, "BO 0" if you are using the FDC, and RETURN. CP/M-68K boots and begins running.

All Information Presented Here is Proprietary to Digital Research

6.3 Bringing Up CP/M-68K Using the S-record Files

The CP/M-68K distribution disks contain two copies of the CP/M-68K operating system in Motorola S-record form, for use in getting your first CP/M-68K system running. S-records (described in detail in Appendix F) are a simple ASCII representation for absolute programs. The two S-record systems contain the CCP and BDOS, but no BIOS. One of the S-record systems resides at locations 400H and up, the other is configured to occupy the top of a 128K memory space. (The exact bounds of the S-record systems may vary from release to release. There will be release notes and/or a file named README describing the exact characteristics of the S-record systems distributed on your disks.) To bring up CP/M-68K using the S-record files, you need:

- 1) some method of down-loading absolute data into your target system
- 2) a computer capable of reading the distribution disks (a CP/M-based computer that supports standard CP/M 8-inch diskettes)
- 3) a BIOS for your target computer

Given the above items, you can use the following procedure to bring a working version of CP/M-68K into your target system:

- 1) You must patch one location in the S-record system to link it to your BIOS's `_init` entry point. This location will be specified in release notes and/or in a README file on your distribution disks. The patch simply consists of inserting the address of the `_init` entry in your BIOS at one long word location in the S-record system. This patching can be done either before or after down-loading the system, whichever is more convenient.
- 2) Your BIOS needs the address of the `_ccp` entry point in the S-record system. This can be obtained from the release notes and/or the README file.
- 3) Down-load the S-record system into the memory of your target computer.
- 4) Down-load your BIOS into the memory of your target computer.
- 5) Begin executing instructions at the first location of the down-loaded S-record system.

Now that you have a working version of CP/M-68K, you can use the tools provided with the distribution system for further development.

End of Section 6

All Information Presented Here is Proprietary to Digital Research

Section 7

7.1 Overview

The Cold Boot Automatic Command Execution feature of CP/M-68K allows you to configure CP/M-68K so that the CCP will automatically execute a predetermined command line on cold boot. This feature can be used to start up turn-key systems, or to perform other desired operations.

7.2 Setting up Cold Boot Automatic Command Execution

The CBACE feature uses two global symbols: `_autost`, and `_usercmd`. These are both defined in the CCP, which uses them on cold boot to determine whether this feature is enabled. If you want to have a CCP command automatically executed on cold boot, you should include code in your BIOS's `_init` routine (which is called at cold boot) to do the following:

- 1) The byte at autost must be set to the value 01H.
- 2) The command line to be executed must be placed in memory at usercmd and subsequent locations. The command must be terminated with a NULL (00H) byte, and may not exceed 128 bytes in length. All alphabetic characters in the command line should be upper-case.

Once you write a BIOS that performs these two functions, you can build it into a CPM.SYS file as described in Section 2. This system, when booted, will execute the command you have built into it.

End of Section 7

Section 8

The PUTBOOT Utility

8.1 PUTBOOT Operation

The PUTBOOT utility is used to copy information (usually a bootstrap loader system) onto the system tracks of a disk. Although PUTBOOT can copy any file to the system tracks, usually the file being written is a program (the bootstrap system).

8.2 Invoking PUTBOOT

Invoke PUTBOOT with a command of the form:

```
PUTBOOT [-H] <filename> <drive>
```

where

- -H is an optional flag discussed below;
- <filename> is the name of the file to be written to the system tracks;
- <drive> is the drive specifier for the drive to which <filename> is to be written (letter in the range A-P.)

PUTBOOT writes the specified file to the system tracks of the specified drive. Sector skewing is not used; the file is written to the system tracks in physical sector number order.

Because the file that is written is normally in command file format, PUTBOOT contains special logic to strip off the first 28 bytes of the file whenever the file begins with the number 601AH, the magic number used in command files. If, by chance, the file to be written begins with 601AH, but should not have its first 28 bytes discarded, the -H flag should be specified in the PUTBOOT command line. This flag tells PUTBOOT to write the file verbatim to the system tracks.

PUTBOOT uses BDOS calls to read <filename>, and used BIOS calls to write <filename> to the system tracks. It refers to the OFF and SPT parameters in the Disk Parameter Block to determine how large the system track space is. The source and command files for PUTBOOT are supplied on the distribution disks for CP/M-68K.

End of Section 8

Appendix A

Contents of Distribution Disks

This appendix briefly describes the contents of the disks that contain CP/M-68K as distributed by Digital Research.

Table A-1. Distribution Disk Contents

File	Contents
AR68.REL	Relocatable version of the archiver/librarian.
AS68INIT	Initialization file for assembler--see AS68 documentation in the <u>CP/M-68K Operating System Programmer's Guide</u> .
AS68.REL	Relocatable version of the assembler.
ASM.SUB	Submit file to assemble an assembly program with file type .S, put the object code in filename.O, and a listing file in filename.PRN.
BIOS.O	Object file of BIOS for EXORMacs.
BIOS.C	C language source for the EXORMacs BIOS as distributed with CP/M-68K.
BIOSA.O	Object file for assembly portion of EXORMacs BIOS.
BIOSA.S	Source for the assembly language portion of the EXORMacs BIOS as distributed with CP/M-68K.
BIOSTYPS.H	Include file for use with BIOS.C.
BOOTER.O	Object for EXORMacs bootstrap.
BOOTER.S	Assembly boot code for the EXORMacs.
C.SUB	Submit file to do a C compilation. Invokes all three passes of the C compiler as well as the assembler. You can compile a C program with the line: A>C filename.
C068.REL	Relocatable version of the C parser.
C168.REL	Relocatable version of the C code generator.

Table A-1. (continued)

File	Contents
CLIB	The C run-time library.
CLINK.SUB	Submit file for linking C object programs with the C run-time library.
CP68.REL	Relocatable version of the C preprocessor.
CPM.H	Include file with C definitions for CP/M-68K. See the <u>C Programming Guide for CP/M-68K</u> for details.
CPM.REL	Relocatable version of CPM.SYS.
CPM.SYS	CP/M-68K operating system file for the EXORMacs.
CPMLIB	Library of object files for CP/M-68K. See Section 2.
CPMLDR.SYS	The bootstrap loader for the EXORMacs. A copy of this was written to the system tracks using PUTBOOT.
CTYPE.H	Same as above.
DDT.REL	Relocatable version of the preloader for DDT™. (Loads DDT1 into the high end of the TPA.)
DDT1.68K	This is the real DDT that gets loaded into the top of the TPA. It is relocatable even though the file type is .68K, because it must be relocated to the top of the TPA each time it is used.
DUMP.REL	Relocatable version of the DUMP utility.
ED.REL	Relocatable version of the ED utility.
ELDBIOS.S	Assembly language source for the ERG sample loader BIOS.
ERGBIOS.S	Assembly language source for the ERG sample BIOS.
ERRNO.H	Same as above.
FORMAT.REL	Relocatable disk formatter for the Motorola EXORMacs.

Table A-1. (continued)

File	Contents
FORMAT.S	Assembly language source for the FORMAT utility.
INIT.REL	Relocatable version of the INIT utility.
INIT.S	Assembly language source, for the INIT utility.
LCPM.SUB	Submit file to create CPM.REL for EXORMacs.
LDBIOS.O	Object file of loader BIOS for EXORMacs.
LDBIOSA.O	Object file for assembly portion of EXORMacs loader BIOS.
LDBIOSA.S	Source for the assembly language portion of the EXORMacs loader BIOS as distributed with CP/M-68K.
LDRLIB	Library of object files for creating a Bootstrap Loader. See Section 3.
LO68.REL	Relocatable version of the linker.
LOADBIOS.H	Include file for use with BIOS.C, to make it into a loader BIOS.
LOADBIOS.SUB	Submit file to create loader BIOS for EXORMacs.
MAKELDR.SUB	Submit file to create CPMLDR.SYS on EXORMacs.
NORMBIOS.H	Include file for use with BIOS.C, to make it into a normal. BIOS
NORMBIOS.SUB	Submit file to create normal BIOS for EXORMacs.
NM68.REL	Relocatable version of the symbol table dump utility.
PIP.REL	Relocatable version of the PIP utility.
PORTAB.H	Same as above.
PUTBOOT.REL	Relocatable version of the PUTBOOT utility.

Table A-1. (continued)

File	Contents
PUTBOOT.S	Assembly language source for the PUTBOOT utility.
README.TXT	ASCII file containing information relevant to this shipment of CP/M-68K. This file might not be present.
RELCPM.SUB	Submit file to relocate CPM.REL into CPM.SYS.
RELOC.REL	Relocatable version of the command file relocation utility.
RELOCx.SUB b	This file is included on each disk that contains .REL command files. (x is the number of the distribution disk containing the files). It is a submit file which will relocate the .REL files for the target system.
S.O	Startup routine for use with C programs-- must be first object file linked.
SEND68.REL	Relocatable version of the S-record creation utility.
SETJMP.H	Same as above.
SIGNAL.H	Same as above.
SIZE68.REL	Relocatable version of the SIZE68 utility.
SR128K.SYS	S-record version of CP/M-68K. This version has no BIOS, and is provided for use in porting CP/M-68K to new hardware.
SR400.SYS	S-record version of CP/M-68K. This version has no BIOS, and is provided for use in porting CP/M-68K to new hardware.
STAT.REL	Relocatable version of the STAT utility.
STDIO.H	Include file with standard I/O definitions for use with C programs. See the C Programming Guide for CP/M-68K for details.

Appendix D

EXORmacs BIOS Written in C

This Appendix contains several files in addition to the C BIOS proper. First, the C BIOS includes conditional compilation to make it into either a loader BIOS or a normal BIOS, and there is an include file for each possibility. One of these include files should be renamed `BIOS_TYPE.H` before compiling the BIOS. The choice of which file is used as `BIOS_TYPE.H` determines whether a normal or loader BIOS is compiled. Both the normal and the loader BIOSes need assembly language interfaces, and they are not the same. Both assembly interface modules are given. Finally, there is an include file that defines some standard variable types.

BIOS.C

This is the main text of the C language BIOS for the EXORmacs.

Appendix F Motorola S-Records

F.1 S-record Format

The Motorola S-record format is a method of representing binary memory images in an ASCII form. The primary use of S-records is to provide a convenient form for transporting programs between computers. Since most computers have means of reading and writing ASCII information, the format is widely applicable. The SENDC68 utility provided with CP/M-68K may be used to convert programs into S-record form.

An S-record file consists of a sequence of S-records of various types. The entire content of an S-record is ASCII. When a hexadecimal number needs to be represented in an S-record it is represented by the ASCII characters for the hexadecimal digits comprising the number. Each S-record contains five fields as follows:

Field:	S	type	length	address	data	checksum
Characters:	1	1	2	2, 4 or 6 4, 6 or 8	variable	2

Figure F-1. S-record Fields

The field contents are as follows:

Table F-1. S-record Field Contents

Field	Contents
S	The ASCII Character 'S'. This signals the beginning of the S-record.
type	A digit between 0 and 9, represented in ASCII, with the exceptions that 4 and 6 are not allowed. Type is explained in detail below.

All Information Presented Here is Proprietary to Digital Research

Table F-1. (continued)

Field	Contents
length	The number of character pairs in the record, excluding the first three fields. (That is, one half the number of characters total in the address, data, and checksum fields.) This field has two hexadecimal digits, representing a one byte quantity.
address	The address at which the data portion of the record is to reside in memory. The data goes at this address and successively higher numbered addresses. The length of this field is determined by the record type.
data	The actual data to be loaded into memory, with each byte of data represented as a pair of hexadecimal digits, in ASCII.
checksum	A checksum computed over the length, address, and data fields. The checksum is computed by adding the values of all the character pairs (each character pair represents a one-byte quantity) in these fields, taking the one's complement of the result, and finally taking the least significant byte. This byte is then represented as two ASCII hexadecimal digits.

F.2 S-record Types

There are eight types of S-records. They can be divided into two categories: records containing actual data, and records used to define and delimit groups of data-containing records. Types 1, 2, and 3 are in the first category, and the rest of the types are in the second category. Each of the S-record types is described individually below.

Table F-2. S-record Types

Type	Meaning
0	This type is a header record used at the beginning of a group of S-records. The data field may contain any desired identifying information. The address field is two bytes (four S-record characters) long, and is normally zero.
1	This type of record contains normal data. The address field is two bytes long (four S-record characters).
2	Similar to Type 1, but with a 3-byte (six S-record characters) address field.
3	Similar to Type 1, but with a 4-byte (eight S-record characters) address field.
5	This record type indicates the number of Type 1, 2, and 3 records in a group of S-records. The count is placed in the address field. The data field is empty (no characters).
7	This record signals the end of a block of type 3 S-records. If desired, the address field is 4 bytes long (8 characters), and may be used to contain an address to which to pass control. The data field is empty.
8	This is similar to type 7 except that it ends a block of type 2 S-records, and its address field is 3 bytes (6 characters) long.
9	This is similar to type 7 except that it ends a block of type 1 S-records, and its address field is 2 bytes (4 characters) long.

S-records are produced by the SENDC68 utility program (described in the CP/M-68K Operating System Programmer's Guide).

End of Appendix F

Appendix G

CP/M-68K Error Messages

This appendix lists the error messages returned by the internal components of CP/M-68K: BDOS, BIOS, and CCP, and by the CP/M-68K system utility, PUTBOOT. The BIOS error messages listed here are specific to the EXORMacs BIOS distributed by Digital Research. BIOSes for other hardware might have different error messages which should be documented by the hardware vendor.

The error messages are listed in Table G-1 in alphabetic order with explanations and suggested user responses.

Table G-1. CP/M-68K Error Messages

Message	Meaning
bad relocation information bits	CCP. This message is a result of a BDOS Program Load Function (59) error. It indicates that the file specified in the command line is not a valid executable command file, or that the file has been corrupted. Ensure that the file is a command file. <u>The CP/M-68K Operating System Programmer's Guide</u> describes the format of a command file. If the file has been corrupted, reassemble or recompile the source file, and relink it before you reenter the command line.
BIOS ERROR -- DISK X NOT SUPPORTED	BIOS. The disk drive indicated by the variable "X" is not supported by the BIOS. The BDOS supports a maximum of 16 drives, lettered A through P. Check the documentation provided by the manufacturer for your particular system configuration to find out which of the BDOS drives your BIOS implements. Specify the correct drive code and reenter the command line.

Table G-1. (continued)

Message	Meaning
BIOS ERROR -- Invalid Disk Status	<p>BIOS. The disk controller returned unexpected or incomprehensible information to the BIOS. Retry the operation. If the error persists, check the hardware. If the error does not come from the hardware, it is caused by an error in the internal logic of the BIOS. Contact the place you purchased your system for assistance. You should provide the information below.</p> <ol style="list-style-type: none"> 1) Indicate which version of the operating system you are using. 2) Describe your system's hardware configuration. 3) Provide sufficient information to reproduce the error. Indicate which program was running at the time the error occurred. If possible, you should also provide a disk with a copy of the program.
Buffer Overflow	<p>PUTBOOT. The bootstrap file will not fit in the PUTBOOT bootstrap buffer. PUTBOOT contains an internal buffer of approximately 16K bytes into which it reads the bootstrap file. Either make the bootstrap file smaller so that it will fit into the buffer, or change the size of the PUTBOOT buffer. The PUTBOOT source code is supplied with the system distributed by DRI. Equate bufsize (located near the front of the PUTBOOT source code) to the required dimension in Hexidecimals. Reassemble and relink the source code before you reenter the PUTBOOT command line.</p>
Cannot Open Source File	<p>PUTBOOT. PUTBOOT cannot locate the source file. Ensure that you specify the correct drive code and filename before you reenter the PUTBOOT command line.</p>

Table G-1. (continued)

Message	Meaning				
CP/M Disk change error on drive x	<p>BDOS. The disk in the drive indicated by the variable x is not the same disk the system logged in previously. When the disk was replaced you did not enter a CTRL-C to log in the current disk. Therefore, when you attempted to write to, erase, or rename a file on the current disk, the BDOS set the drive status to read-only and warm booted the system. The current disk in the drive was not overwritten. The drive status was returned to read-write when the system was warm booted. Each time a disk is changed, you must type a CTRL-C to log in the new disk.</p>				
CP/M Disk file error: filename is read-only. Do you want to: Change it to read/write (C), or Abort (A)?	<p>BDOS. You attempted to write to, erase, or rename a file whose status is read-only. Specify one of the options enclosed in parentheses. If you specify the C option, the BDOS changes the status of the file to read-write and continues the operation. The read-only protection previously assigned to the file is lost.</p> <p>If you specify the A option or a CTRL-C, the program terminates and CPM-68K returns the system prompt.</p>				
CP/M Disk read error on drive x Do you want to: Abort (A), Retry (R), or Continue with bad data (C)?	<p>BDOS. This message indicates a hardware error. Specify one of the options enclosed in parentheses. Each option is described below.</p> <table> <tr> <th>Option</th><th>Action</th></tr> <tr> <td>A or CTRL-C</td><td>Terminates the operation and CP/M-68K returns the system prompt. (Meaning continued on next page.)</td></tr> </table>	Option	Action	A or CTRL-C	Terminates the operation and CP/M-68K returns the system prompt. (Meaning continued on next page.)
Option	Action				
A or CTRL-C	Terminates the operation and CP/M-68K returns the system prompt. (Meaning continued on next page.)				

Table G-1. (continued)

Message	Meaning
CP/M Disk read error on drive x (continued)	
<u>Option</u>	<u>Action</u>
R	Retries operation. If the retry fails, the system reprompts with the option message.
C	Ignores error and continues program execution. Be careful if you use this option. Program execution should not be continued for some types of programs. For example, if you are updating a data base and receive this error but continue program execution, you can corrupt the index fields and the entire data base. For other programs, continuing program execution is recommended. For example, when you transfer a long text file and receive an error because one sector is bad, you can continue transferring the file. After the file is transferred, review the file, and add the data that was not transferred due to the bad sector.
CP/M Disk write error on drive x Do you want to: Abort (A), Retry (R), or Continue with bad data (C)?	
BDOS. This message indicates a hardware error. Specify one of the options enclosed in parentheses. Each option is described below.	
<u>Option</u>	<u>Action</u>
A or CTRL-C	Terminates the operation and CP/M-68K returns the system prompt.
R	Retries operation. If the retry fails, the system reprompts with the option message (Meaning continued on next page.)

Table G-1. (continued)

Message	Meaning
CP/M Disk write error on drive x (continued)	
<u>Option</u>	<u>Action</u>
C	<p> Ignores error and continues program execution. Be careful if you use this option. Program execution should not be continued for some types of programs. For example, if you are updating a data base and receive this error but continue program execution, you can corrupt the index fields and the entire data base. For other programs, continuing program execution is recommended. For example, when you transfer a long text file and receive an error because one sector is bad, you can continue transferring the file. After the file is transferred, review the file, and add the data that was not transferred due to the bad sector.</p>
<p>CP/M Disk select error on drive x Do you want to: Abort (A), Retry (R)</p> <p>BDOS. There is no disk in the drive or the disk is not inserted correctly. Ensure that the disk is securely inserted in the drive. If you enter the R option, the system retries the operation. If you enter the A option or CTRL-C the program terminates and CPM-68K returns the system prompt.</p>	
<p>CP/M Disk select error on drive x</p> <p>BDOS. The disk selected in the command line is outside the range A through P. CP/M-68K can support up to 16 drives, lettered A through P. Check the documentation provided by the manufacturer to find out which drives your particular system configuration supports. Specify the correct drive code and reenter the command line.</p>	

Table G-1. (continued)

Message	Meaning
File already exists	<p>CCP. This error occurs during a REN command. The name specified in the command line as the new filename already exists. Use the ERA command to delete the existing file if you wish to replace it with the new file. If not, select another filename and reenter the REN command line.</p>
insufficient memory or bad file header	<p>CCP. This error could result from one of three causes:</p> <ol style="list-style-type: none"> 1) The file is not a valid executable command file. Ensure that you are requesting the correct file. This error can occur when you enter the filename before you enter the command for a utility. Check the appropriate section of the <u>CP/M-68K Operating System Programmer's Guide</u> or the <u>CP/M-68K Operating System User's Guide</u> for the correct command syntax before you reenter the command line. If you are trying to run a program when this error occurs, the program file may have been corrupted. Reassemble or recompile the source file and relink it before you reenter the command line. 2) The program is too large for the available memory. Add more memory boards to the system configuration, or rewrite the program to use less memory. 3) The program is linked to an absolute location in memory that cannot be used. The program must be made relocatable, or linked to a usable memory location. The BDOS Get/Set TPA Limits Function (63) returns the high and low boundaries of the memory space that is available for loading programs.

Table G-1. (continued)

Message	Meaning
Invalid Command Line	<p>PUTBOOT. Either the command line syntax is incorrect, or you have selected a disk drive code outside the range A through P. Refer to the section in this manual on the PUTBOOT utility for a full description of the command line syntax. The CP/M-68K BDOS supports 16 drives, lettered A through P. The BIOS may or may not support all 16 drives. Check the documentation provided by the manufacturer for your particular system configuration to find out which drives your BIOS supports. Specify a valid drive code before reentering the PUTBOOT command line.</p>
No file	<p>CCP. The filename specified in the command line does not exist. Ensure that you use the correct filename and reenter the command line.</p>
No wildcard filenames	<p>CCP. The command specified in the command line does not accept wildcards in file specifications. Retype the command line using a specific filename.</p>
Program Load Error	<p>CCP. This message indicates an undefined failure of the BDOS Program Load Function (59). Reboot the system and try again. If the error persists, then it is caused by an error in the internal logic of the BDOS. Contact the place you purchased your system for assistance. You should provide the information below.</p> <ol style="list-style-type: none">1) Indicate which version of the operating system you are using.2) Describe your system's hardware configuration. (Meaning continued on next page.)

Table G-1. (continued)

Message	Meaning
	3) Provide sufficient information to reproduce the error. Indicate which program was running at the time the error occurred. If possible, you should also provide a disk with a copy of the program.
read error on program load	CCP. This message indicates a premature end-of-file. The file is smaller than the header information indicates. Either the file header has been corrupted or the file was only partially written. Reassemble or recompile the source file, and relink it before you reenter the command line.
Select Error	PUTBOOT. This error is returned from the BIOS select disk function. The drive specified in the command line is either not supported by the BIOS, or is not physically accessible. Check the documentation provided by the manufacturer to find out which drives your BIOS supports. This error is also returned if a BIOS supported drive is not supported by your system configuration. Specify a valid drive and reenter the PUTBOOT command line.
SUB file not found	CCP. The file requested either does not exist, or does not have a filetype of SUB. Ensure that you are requesting the correct file. Refer to the section on SUBMIT in the <u>CP/M-68K Operating System User's Guide</u> for information on creating and using submit files.
Syntax: REN newfile=oldfile	CCP. The syntax of the REN command line is incorrect. The correct syntax is given in the error message. Enter the REN command followed by a space, then the new filename, followed immediately by an equals sign (=) and the name of the file you want to rename.

All Information Presented Here is Proprietary to Digital Research

Table G-1. (continued)

Message	Meaning
Too many arguments:	argument?
	<p>CCP. The command line contains too many arguments. The extraneous arguments are indicated by the variable argument. Refer to the <u>CP/M-68K Operating System User's Guide</u> for the correct syntax for the command. Specify only as many arguments as the command syntax allows and reenter the command line. Use a second command line for the remaining arguments, if appropriate.</p>
Too Much Data for System Tracks	<p>PUTBOOT. The bootstrap file is too large for the space reserved for it on the disk. Either make the bootstrap file smaller, or redefine the number of tracks reserved on the disk for the file. The number of tracks reserved for the bootstrap file is controlled by the OFF parameter in the disk parameter block in the BIOS.</p> <p>This error can also be caused by a bootstrap file that contains a symbol table and relocation bits. To find out if the bootstrap program will fit on the system tracks without the symbol table and relocation bits, use the SIZE68 Utility to display the amount of space the bootstrap program occupies. The first and second items returned by the SIZE68 Utility are the amount of space occupied by the text and data, respectively. The third item returned is the amount of space occupied by the BSS. The sum of the first two items, or the total minus the third item, will give you the amount of space required for the bootstrap program on the system tracks. Compare the amount of space your bootstrap program requires to the amount of space allocated by the OFF parameter.</p> <p>Because the symbol table and relocation bits are at the end of the file, the bootstrap program may have been entirely written to the system tracks and you can ignore this message. Or, you can run RELOC on the bootstrap file to remove the symbol table and relocation bits from the bootstrap file and reenter the PUTBOOT command line.</p>

Table G-1. (continued)

Message	Meaning
User # range is [0-15]	CCP. The user number specified in the command line is not supported by the BIOS. The valid range is enclosed in the square brackets in the error message. Specify a user number between 0 and 15 (decimal) when you reenter the command line.
Write Error	PUTBOOT. Either the disk to which PUTBOOT is writing is damaged or there is a hardware error. Insert a new disk and reenter the PUTBOOT command line. If the error persists, check for a hardware error.
